

Does the electro-optical module need configuration

Overview

An electro-optic modulator (EOM) is an optical device in which a signal-controlled element exhibiting an electro-optic effect is used to modulate a beam of light. The modulation may be imposed on the phase, frequency, amplitude, or polarization of the beam. Modulation bandwidths extending into the gigahertz range are possible with the use of laser-controlled modulators. The electro-optic phase modulation (PM) is a modulation pattern that encodes information as variations in the instantaneous phase of a signal. A phase modulating EOM can also be used as an amplitude modulator by using a half-wave plate. This alternative technique is often used in applications where the requirements of phase stability are not as stringent. Depending on the type and orientation of the nonlinear crystal, and on the direction of the applied electric field, the phase delay can depend on the polarization direction. A phase modulator can thus be seen as a voltage-controlled device.
