

Does the network require a switch

Overview

Homes and small offices need routers for Internet access, but most do not need a network switch, unless they require a large amount of Ethernet* ports. A network switch connects devices within a network (often a local area network, or LAN *) and forwards data packets to and from those devices. Unlike a router, a switch only sends data to the single device it is intended for (which may be another switch, a router, or a user's computer), not to. The Switch is a network device that is used to segment the networks into different subnetworks called subnets or LAN segments. Note that expensive "managed" switches, which are. Switching in IT and computer networking is the transfer of data packets, or blocks of data, through a network switch. A network switch is a multiport network. While a router connects multiple devices to the internet and allows for communication between them, a switch can provide additional Ethernet ports for wired connections, allowing for faster data transfer speeds and more stable connections. A switch can also help distribute network traffic.
