

Optical Module dmleml

Overview

In the introduction of product parameters of optical modules, we often mention the modulation mode as a key indicator, DML (Directly Modulation Laser) and EML (External Modulation Laser) are two major modulation technologies for optical modules. Below is a simplified working principle diagram: Figure 3 Working Principle Diagram of Optical Transceiver The optical signal transmitted through optical fibers is not constant; instead, it is a modulated signal with varying intensity. The characteristics and application differences between DML and EML are as follows: A DFB laser generates a continuous optical carrier under a steady bias current. Next to it sits an electro-absorption modulator (EAM). The key idea is simple: the laser runs steadily, while modulation. EML laser, which stands for Electro-absorption Modulated Laser, operates based on the electro-absorption effect. EML lasers combine the high-speed performance. DML refers to a directly modulated laser. This laser is also called a distributed-feedback laser diode (DFB) since it uses a distributed feedback structure. A DML uses a single chip with a simple electrical circuit design, so it can be an optimal choice for a compact circuit configuration with low power consumption. Both EML (External Cavity Laser) and DML (Distributed Feedback Laser) lasers play an important role in optical modules for optical communications and other optoelectronic applications.
