

Optical cable UV protection

Overview

UV-curable coatings provide protection, flexibility and strength to the fiber as it is drawn. UV inks color code the optical fibers and protect the fibers against decomposition caused by cable gels, particularly in the case of multiple-fiber cable production. They are usually black because the plastic contains soot. Soot absorbs the high-energy UV rays on the surface and converts them into heat. The cable therefore warms up and must therefore have a sufficiently high. UV-resistant fiber optic cables are a fundamental component in the design of reliable outdoor telecommunications infrastructure, where long-term exposure to sunlight and environmental stress cannot be avoided. In modern network deployments such as FTTH, inter-building connectivity, industrial. These are cables designed primarily for internal installation (e. Twin Flat cables) and will offer limited resistance to UV exposure. In general, different fibre types can be classified.
